HTMLFormElement.reset()

HTMLFormElement.reset()

The HTMLFormElement.reset() method restores a form element's default values. This method does the same thing as clicking the form's <input type="reset"> control.

```
HTMLFormElement.reset()          form                                    .
         form   <input type="reset">                                           .
```

If a form control (such as a reset button) has a name or id of reset it will mask the form's reset method. It does not reset other attributes in the input, such as disabled.

```
reset                form           reset           id              , form   reset
              (?          )                        )
input              ,          disabled              reset            .
```

Note that if setAttribute() is called to set the value of a particular attribute, a subsequent call to reset() won't reset the attribute to its default value, but instead will keep the attribute at whatever value the setAttribute() call set it to.

setAttribute()   **, reset()**   **reset()**
        ,
    setAttribute()   .

                                            ,   (   )   –
    –
              ,   ,   (   )
         .

form   .

                                        , form   +

    ,
    input   .
